Goal

Using a
Genetic
Algorithm to
Optimize Steel
Structures

Joseph Brown

Goals/Strategy

The Model

Evolution

This isn't over
yet!

- Simulate the physics on a steel structure
- Determine some metric of “fitness” for these structures
- Systematically breed and cull a population based on this metric.

Modeling the Tower

Structures

Joseph Brown

Goals/Strategy

The Model

Evolution

This isn't over
yet!

Steel beams are modeled as springs with a dampening force. Forces cause the beam to expand or contract, but it will tend to draw its endpoints to a predetermined distance. Each junction is modeled as an angular spring, pushing or pulling beams at that junction to a predetermined angle.

Each tower has a folder containing three files. One file holds the position of each of its nodes, and whether each node is an anchor point. A second file holds the information about the beams, including which two nodes are at the ends of the beam, and what the length and spring constant of the beam are. A third file holds information about angles between beams, and what the angular spring constants are for those junctions.

A screenshot of a terminal window titled "Terminal". The window displays a 10x5 grid of numbers, likely representing a genome or configuration matrix. The numbers are color-coded: yellow for rows 1 through 10, and black for columns 6 through 10. The grid is as follows:

1	Nodes: 30				
2	Max Connections: 20				
3					
4	beam1				
5	6	10	11	14	
6	17	19	20	21	24
7	25	28			
8	6	9	10	11	
9	12	14	16	17	18
10	19	20	23	26	27
11	7	8	9	10	
12	11	13	17	19	23
13	24	25	26	27	29
14	6	8	10	16	
15	17	18	19	21	23
16	26	28	29		
17	9	10	11	13	
18	14	16	17	20	23
19	25	27	29		
20	6	7	11	12	
21	16	18	20	21	25

We have a bunch of nodes connected by springs. We know how the connections are organized, and we know where each of the beams are connected.

By alternately calculating the forces on each node and updating their positions and velocity, we can see how the structure responds to gravity and other external forces. Using parallel processing on the graphics cards in Dr. Wyatt's lair, I've sped this up a lot.

Population steps

- 1 Random Initialization
- 2 Let structures stabilize and add them to the main population.
- 3 Remove all structures that have a fitness less than the median.
- 4 Choose stable structures to be parents based on fitness.
- 5 Mutate parents to produce children.
- 6 Let children structures reach a stable state, and add them to the main population.
- 7 Repeat steps 3-6 until a generation goal is reached.
